Scientific Programming Practical 5

Introduction

Continue - Break

Sometimes it is useful to skip an entire iteration of a loop or end the loop before its supposed end. This can be achieved with two different statements: **continue** and **break**.

Continue

Within a **for** or **while** loop, **continue** makes the interpreter skip that iteration and move to the next.

Example: Print all the odd numbers from 1 to 20.

```
#Two equivalent ways
#1. Testing remainder == 1
for i in range(21):
    if(i % 2 == 1):
        print(i, end = " ")

print("")

#2. Skipping if remainder == 0 in for
for i in range(21):
    if(i % 2 == 0):
        continue
    print(i, end = " ")

1 3 5 7 9 11 13 15 17 19
1 3 5 7 9 11 13 15 17 19
```

Continue

Continue can be used also within while loops but we need to be careful and remember to update the value of the variable before reaching the continue statement or we will get stuck in never-ending loops.

Example: Print all the odd numbers from 1 to 20.

```
#Wrong code:
i = 0
while (i < 21):
    if(i % 2 == 0):
        continue
    print(i, end = " ")
    i = i + 1 # NEVER EXECUTED IF i % 2 == 0!!!!</pre>
```

Continue

Continue can be used also within while loops but we need to be careful and remember to update the value of the variable before reaching the continue statement or we will get stuck in never-ending loops.

Example: Print all the odd numbers from 1 to 20.

Break

Example: Pick a random number from 1 and 50 and count how many times it takes to randomly choose number 27. Limit the number of random picks to 40 (i.e. if more than 40 picks have been done and 27 has not been found exit anyway with a message).

Within a **for** or **while** loop, **break** makes the interpreter exit the loop and continue with the sequential execution.

Sometimes it is useful to get out of the loop if to complete our task we do not need to get to the end of the loop.

```
import random

iterations = 1
while(iterations <= 40):
    pick = random.randint(1,50)
    if(pick == 27):
        break
    iterations += 1

if(iterations == 41):
    print("Sorry number 27 was never found!")
else:
    print("27 found in ", iterations, "iterations")

Sorry number 27 was never found!</pre>
```

Break

Example: Pick a random number from 1 and 50 and count how many times it takes to randomly choose number 27. Limit the number of random picks to 40 (i.e. if more than 40 picks have been done and 27 has not been found exit anyway with a message).

```
1mport random
                                                       import random
                                                       found = False # This is called flag
iterations = 1
                                                       iterations = 1
while(iterations <= 40):</pre>
                                                       while(iterations <= 40 and found == False): #the flag is used to exit
    pick = random.randint(1,50)
                                                           pick = random.randint(1,50)
    if(pick == 27):
                                                           1f(pick == 27):
        break
                                                               found = True
                                                                               #update the flag, will exit at next iteration
    iterations += 1
                                                           iterations += 1
if(iterations == 41):
                                                       if(iterations == 41):
    print("Sorry number 27 was never found!")
                                                           print("Sorry number 27 was never found!")
                                                       else:
else:
                                                           print("27 found in ", iterations, "iterations")
    print("27 found in ", iterations, "iterations")
                                                       Sorry number 27 was never found!
Sorry number 27 was never found!
```

Using breaks of flags....

List comprehension

List comprehension is a quick way of creating a list. The resulting list is normally obtained by applying a function or a method to the elements of another list that **remains unchanged**.

```
new_list = [ some_function (x) for x in start_list if condition]

or

new_list = [ x.some_method() for x in start_list if condition]
```

List comprehension

Example: Given a list of strings ["dog", "cat", "rabbit", "guinea pig", "hamster", "canary", "goldfish"] create a list with the elements starting with a "c" or "g".

```
pets = ["dog", "cat", "rabbit", "guinea pig", "hamster", "canary", "goldfish"]

cg_pets = [x for x in pets if (x.startswith("c") or x.startswith("g"))]

print(pets)
print(cg_pets)

['dog', 'cat', 'rabbit', 'guinea pig', 'hamster', 'canary', 'goldfish']
['cat', 'guinea pig', 'canary', 'goldfish']
```

A dictionary is a map between one object, the key and another object, the value. Dictionaries are mutable objects and contain sequences of mappings key -> object but there is not specific ordering among them. Dictionaries are defined using the curly braces {key1 : value1, key2 : value2} and : to separate keys from values.

```
first dict = {"one" : 1, "two": 2, "three" : 3, "four" : 4}
print("First:", first dict)
empty dict = dict()
print("Empty:",empty dict)
second dict = {1 : "one", 2 : "two", "three" :3 } #BAD IDEA BUT POSSIBLE!!!
print(second dict)
third dict = dict(zip(["one", "two", "three", "four"],[1,2,3,4]))
print(third dict)
print(first dict == third dict)
First: {'three': 3, 'one': 1, 'four': 4, 'two': 2}
Empty: {}
{1: 'one', 2: 'two', 'three': 3}
{'three': 3, 'one': 1, 'four': 4, 'two': 2}
True
```

Keys must be immutable objects

```
a = (1,2,3) #a,b are tuples: hence immutable
b = (1,3,5)
my_dict = {a : 6, b : 9 }
print(my dict)
c = [1,2,3] #c,d are lists: hence mutable
d = [1,3,5]
dict2 = \{c : 6, d : 9\}
print(dict2)
\{(1, 3, 5): 9, (1, 2, 3): 6\}
TypeError
                                          Traceback (most recent call last)
<ipython-input-49-0fe98c7f5acd> in <module>()
     8 d = [1,3,5]
---> 10 dict2 = {c : 6, d : 9}
     11 print(dict2)
TypeError: unhashable type: 'list'
```

Functions on dictionaries

Result	Operator	Meaning
bool	obj in dict	Return True if a key is present in the dictionary
int	len(dict)	Return the number of elements in the dictionary
obj	dict[obj]	Read the value associate with a key
	dict[obj] = obj	Add or modify the value associated with a key

```
myDict = {"one" : 1, "two" : 2, "twentyfive" : 25}
print(myDict)
myDict["ten"] = 10
myDict["twenty"] = 20
print(myDict)
print("The dictionary has ", len(myDict), " elements")
print("The value of \"ten\" is:", myDict["ten"])
print("The value of \"two\" is:", myDict["two"])
print("Is \"twentyfive\" in dictionary?", "twentyfive" in myDict)
print("Is \"seven\" in dictionary?", "seven" in myDict)
{'one': 1, 'twentyfive': 25, 'two': 2}
{'one': 1, 'twentyfive': 25, 'ten': 10, 'two': 2, 'twenty': 20}
The dictionary has 5 elements
The value of "ten" is: 10
The value of "two" is: 2
Is "twentyfive" in dictionary? True
Is "seven" in dictionary? False
```

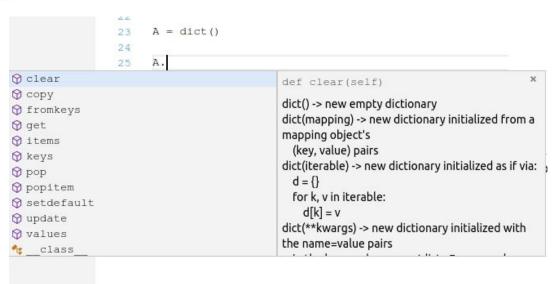

Methods of dictionaries

Return	Method	Meaning
list	dict.keys()	Returns the list of the keys that are present in the dictionary
list	dict.values()	Returns the list of the values that are present in the dictionary
list of tuples	dict.items()	Returns the list of pairs (key, value) that are present in the dictionary

ERRATUM: dict.keys() returns a dict_keys object not a list. To cast it to list, we need to call list(dict.keys()).

Method Return Meaning Returns the list of the keys that dict.keys() list are present in the dictionary Returns the list of the values that list dict.values() are present in the dictionary dict.items() Returns the list of pairs (key, list of value) that are present in the tuples dictionary

Use the in-line help...

Example Given the protein sequence below, store in a dictionary all the aminoacids present and count how many times they appear. Finally print out the stats (e.g. how many amino-acids are present, the most frequent, the least frequent and the frequency of all of them **in alphabetical order**).

```
MGNAAAAKKGSEQESVKEFLAKAKEDFLKKWENPAQNTAHLDQFERIK
The number of amino-acids present is 20
A is present 23 times
C is present 2 times
D is present 18 times
E is present 27 times
F is present 25 times
G is present 22 times
H is present 9 times
I is present 21 times
K is present 34 times
L is present 32 times
M is present 8 times
N is present 17 times
P is present 14 times
Q is present 14 times
R is present 15 times
S is present 16 times
T is present 14 times
V is present 20 times
W is present 6 times
Y is present 14 times
Amino C has the lowest freq. (2)
Amino K has the highest freq. (34)
```

```
protein = """MGNAAAAKKGSEQESVKEFLAKAKEDFLKKWENPAQNTAHLDQFERIKTLGTGSFGRVML
VKHMETGNHYAMKILDKOKVVKLKQIEHTLNEKRILQAVNFPFLVKLEFSFKDNSNLYMV
MEYVPGGEMFSHLRRIGRFSEPHARFYAAQIVLTFEYLHSLDLIYRDLKPENLLIDQQGY
IOVTDFGFAKRVKGRTWTLCGTPEYLAPEIILSKGYNKAVDWWALGVLIYEMAAGYPPFF
ADQPIQIYEKIVSGKVRFPSHFSSDLKDLLRNLLQVDLTKRFGNLKNGVNDIKNHKWFAT
TDWIAIYQRKVEAPFIPKFKGPGDTSNFDDYEEEEIRVSINEKCGKEFSEF"""
protein = protein.replace("\n","")
print(protein)
amino acids = dict()
for a in protein:
    1f( a 1n amino acids):
        amino acids[a] = amino acids[a] + 1
    else:
        amino acids[a] = 1
num aminos = len(amino acids)
print("The number of amino-acids present is ", num aminos)
#let's get all aminoacids
#and sort them alphabetically
a keys = list(amino acids.keys())
a keys.sort()
mostF = {"frequency" : 0, "aminoacid" : "-"}
leastF = {"frequency" : num_aminos, "aminoacid" : "-"}
for a in a keys:
    freq = amino_acids[a]
   if(mostF["frequency"] < freq):</pre>
       mostF["frequency"] = freq
        mostf["aminoacid"] = a
   if(leastF["frequency"] > freq):
       leastF["frequency"] = freq
        leastF["aminoacid"] = a
   print(a, " is present", freq, "times")
print("Amino", leastF["aminoacid"], "has the lowest freq. (",leastF["frequency"],")")
print("Amino", mostF["aminoacid"], "has the highest freq. (",mostF["frequency"],")")
```

Exercises

- 1. Given the following two lists of integers: [1, 13, 22, 7, 43, 81, 77, 12, 15,21, 84,100] and [44,32,7, 100, 81, 13, 1, 21, 71]:
 - Sort the two lists
 - Create a third list as intersection of the two lists (i.e. an element is in the intersection if it is present in both lists).
 - 3. Print the three lists.

Show/Hide Solution

- 2. Given the string "nOBody Said iT was eAsy, No oNe Ever sald it WoulD be tHis hArd..."
 - 1. Create a list with all the letters that are capitalized (use str.isupper)
 - 2. Print the list
 - 3. Use the string method **join** to concatenate all the letters in a string, using "*" as separator. The syntax of join is str.join(list) and it outputs a string with all the elements in list joined with the character in str (es. "+".join([1,2,3]) returns "1+2+3").

The expected output:

```
['O', 'B', 'S', 'T', 'A', 'N', 'N', 'E', 'I', 'W', 'D', 'H', 'A']
O*B*S*T*A*N*N*E*I*W*D*H*A
```

Show/Hide Solution

3. Given the following list of gene correlations:

```
geneCorr = [["G1C2W9", "G1C2Q7", 0.2], ["G1C2W9", "G1C2Q4", 0.9],
["Q6NMS1", "G1C2W9", 0.8], ["G1C2W9", "Q6NMS1", 0.4], ["G1C2Q7", "G1C2Q4", 0.76]]
```
